Abstract
The purpose of this research is to develop an integrated humanitarian logistics system for post-disaster relief response in developing countries, which includes a measure of the suffering of affected people into the formulations of humanitarian logistics. This will allow a better distribution of social costs among those affected, and the timely delivery of critical commodities according to deprivation time, starting with the neediest people. In consequence, this framework leads to more effective and coordinated strategies for delivering critical supplies in developing countries.

Objectives
- To develop humanitarian logistic models capable of explicitly considering the impacts of delivery actions on deprivation costs in developing countries.
- To propose an emergency management system for disaster relief agencies in order to improve their response.

Hypothesis
The suffering of affected people due to disasters
Our hypothesis is that the costs associated to human suffering, due to the occurrence of a disaster, can be assessed based on the time of supply shortages experienced by affected people and their socioeconomic characteristics. The structure and nature of such suffering should be considered as a function of wellness, which is monotonically non-linear and convex (Holguín-Veras et al., 2013) with respect to deprivation time, as shown in Figure 1.

The assignment of humanitarian aid
We believe that incorporating deprivation costs into the objective function of humanitarian logistic models allows to reach the optimal assignment and the timely delivery of scarce resources, during the aftermath of a disaster.

The samples
Two surveys were applied in several cities of Colombia where socioeconomic information was gathered from households affected by natural disasters, and from others who were not. Figure 2 shows the towns (in red) were the first surveys were conducted and the level of impact of floods in the Colombian Caribbean Region in 2010 and 2011. This sample was formed by 240 respondents.

The purpose of water (4 liters per capita) to people affected.
In all scenarios, the fixed cost is COP 7,000,000 for each warehouse and the inventory costs are COP 3,000 for each unit of product (4 liters).

Methods and Instruments

Microeconomic approach
The welfare of an affected individual for a natural disaster can be treated through the random utility theory, using stated preference surveys. (Ortuza and Williamson, 2011).

\[ U(x) = V(x) + \frac{1}{2} \sum_{i=1}^{n} \beta_i \cdot s_{i,j} + \frac{1}{2} \cdot f_2(v_{i1}) \]

The benefits for timely supply are obtained as a measure of welfare change arising from the change in consumer surplus (Train, 2009).

\[ \Delta(E_x) = \frac{1}{dx} \left[ \ln \left( \sum_{i=1}^{n} e_{i,j} \right) - \ln \left( \sum_{i=1}^{n} e_{i,j} \right) \right] \]

Experimental design
The design consisted on choice situations that were presented to respondents, describing hypothetical scenarios of being a disaster survivor where they had to decide whether or not to buy a kit of life-sustaining items (water and foods). The variables used in this experimental design were: Shortage time (no delivery), expected delivery time, budget, purchase amount and total cost of the purchase.

Conclusions
- This research provides basis for efficient delivery strategies, ensuring the best allocation of critical commodities to affected populations.
- We estimated different econometric models of deprivation costs, that can be useful to assess humanitarian relief operations and to develop comprehensive models of humanitarian logistics.
- Progress has been made in developing a strategic logistic model, especially for pre-positioning supplies to serve the areas affected by disasters.

References

Case Study - Numerical example
The example considers three scenarios for distributing water in three towns affected by a disaster. The population of each town is 500 inhabitants.

The second survey was applied to 560 people from different cities and towns affected by disasters in Colombia.

Acknowledgments
The authors wish to thank the program PEER-NSE for supporting this research through funding the project "Integrated humanitarian logistic system for developing countries" and the National Science Foundation for funding the project "Cyber Enabled Discovery System for Advanced Multidisciplinary Study of Humanitarian Logistics for Disaster Response" (NSF-IIS 1124827).

Future research impacts
The development of the research will minimize the negative impacts of natural disasters in terms of human suffering, especially in developing countries. The preliminary results can be briefly summarized in the fact that the estimated costs can be incorporated into comprehensive models of humanitarian logistics, both at the strategic level (facility location for prepositioning supplies) and the tactical or operational level (assignment to the affected), and they serve as support to making decision process related for an efficient response. Results can be used for the economic and social assessment of humanitarian aid operations.
