Current Issues in Planetary Protection

Catharine A. Conley, NASA Planetary Protection Officer

25 May, 2012
2012 NASA Planetary Science Goals

Goal 2: Expand scientific understanding of the Earth and the universe in which we live.

2.3 Ascertain the content, origin, and evolution of the solar system and the potential for life elsewhere.

   2.3.1 Inventory solar system objects and identify the processes active in and among them.

   2.3.2 Improve understanding of how the Sun's family of planets, satellites, and minor bodies originated and evolved.

   2.3.3 Improve understanding of the processes that determine the history and future of habitability of environments on Mars and other solar system bodies.

   2.3.4 Improve understanding of the origin and evolution of Earth's life and biosphere to determine if there is or ever has been life elsewhere in the universe.

   2.3.5 Identify and characterize small bodies and the properties of planetary environments that pose a threat to terrestrial life or exploration or provide potentially exploitable resources.
What are the origins, distribution, and future of life in the universe?
And scattered about... were the Martians—dead!—slain by the putrefactive and disease bacteria against which their systems were unprepared; slain as the red weed was being slain; slain, after all man's devices had failed, by the humblest things that God, in his wisdom, has put upon this earth.

...By virtue of this natural selection of our kind we have developed resisting power; to no germs do we succumb without a struggle...
Early Concerns: Protecting Science during Space Exploration

Moondust

The study of this covering layer by space vehicles may offer clues to the biochemical origin of life.

Joshua Lederberg and Dean B. Cowie

“...we urgently need to give some thought to the conservative measures needed to protect future scientific objectives on the moon and the planets”
Over 50 Years of International Effort

- 1956, Rome: International Astronautical Foundation meets to discuss lunar and planetary contamination
- Feb. 1958: International Council for Science (ICSU) forms committee on Contamination by ExtraTerrestrial EXploration
- June 1958: NAS establishes the SSB
- July 1958: Formation of NASA
- Oct. 1958: Formation of COSPAR by ICSU
- July 1958: Formation of UN-COPUOS
- 1963: NASA acquires the first ‘Planetary Quarantine Officer’ – on loan from the Public Health Service
Preventing Contamination: A ‘Probabilistic’ Formulation

In 1962, the SSB recommended to allow a $1 \times 10^{-4}$ probability of contamination *per mission* – anticipating many missions.

The number of microbes that could survive on a planetary object was based on the initial contamination level $[N_0]$, and reduced by various factors:

$$N_{\text{final}} = N_{\text{initial}} F_1 F_2 F_3 F_\ldots$$

- $F_1$—Total number of cells relative to assayed cells ($N_{X_0}$)
- $F_2$—Bioburden reduction survival fraction, when applied
- $F_3$—Cruise survival fraction
- $F_\ldots$—Additional factors as appropriate for the mission scenario 

$P_{\text{contamination}}$ is set equal to $N_{\text{final}}$

- Factors are organized in chronological order, with the understanding that iteration is necessary
- 'Probability of growth' on Mars, during Viking, was estimated to be $1 \times 10^{-6}$ – we now know it’s a lot closer to 1...
Current International Framework

• The Outer Space Treaty of 1967
  – Proposed to the UN in 1966; Signed in January 1967
  – Ratified by the USSR and US Senate by May, 1967
  – Article IX of the Treaty states that:
    “...parties to the Treaty shall pursue studies of outer space including the Moon and other celestial bodies, and conduct exploration of them so as to avoid their harmful contamination and also adverse changes in the environment of the Earth resulting from the introduction of extraterrestrial matter and, where necessary, shall adopt appropriate measures for this purpose...”

• The Committee on Space Research of the International Council for Science maintains an international consensus policy on planetary protection
  – COSPAR policy represents an international scientific consensus, based on advice from national scientific members, including the US Space Studies Board
  – COSPAR is consultative with the UN (through UN COPUOS and the Office of Outer Space Affairs) on measures to avoid contamination and protect the Earth
  – NASA and ESA policies specify that international robotic missions with agency participation must follow COSPAR policy, as a consensus basis for requirements
Life Affects the Evolution of Planets

Evolution of Earth's Early Environment

- Solar luminosity Percent of modern
- Meteorite impacts Size and frequency
- Heat flow $10^{-6}$ joules $cm^2 sec$
- Continental stabilization Major orogenies

Age, Ga

- Banded Iron Formations
- Oceanic $O_2$ Rise

Atm. $O_2$

- 35%
- 0%
Microbes are Everywhere on Earth

Most organisms live in fairly complex communities, in which members share resources and improve community survival.

Some communities are made up of small numbers of species: frequently found in more ‘extreme’ environments.

- Desulforudis audaxviator
- Rhizocarpon geographicum
- Lichen survives space exposure

Mushroom Spring
Yellowstone National Park

2.8 km²
Introduced Organisms Can Have Ecological Impacts

Most stable communities are resistant to invasion by novel species.

However, sometimes organisms with novel capabilities can sweep through a community.

Salmonella typhimurium express more virulence genes after cultured growth in space.
Life on Earth Keeps Spreading

• Before *Deinococcus radiodurans*, we thought we knew how much radiation organisms could tolerate
• Before *Desulforudis audaxviator* (and their nematode predators), we thought we knew where organisms could live
• Organisms making do in 58 Million year old subsea sediments seem to wait around for a rather long time....
• What is the actual range (and duration) of conditions under which Earth Life can grow? Can tolerate? Can survive?
• Given that we know we keep learning more about life on Earth, how do we ensure that other planets are protected?

How do we compensate for what we don’t know?
Planetary Environments are Diverse

The unaltered surfaces of most planets are cold, and by being cold, are dry. - spacecraft can change this.

Interior environments may be more similar to Earth:
- possible subsurface oceans, both hot and cold
- subsurface rock, similar (?) to inhabited Earth rocks
# Planetary Protection Mission Categories

<table>
<thead>
<tr>
<th>PLANET PRIORITIES</th>
<th>MISSION TYPE</th>
<th>MISSION CATEGORY</th>

</table>
Planetary Protection Mission Constraints

• Depend on the nature of the mission and on the target planet

• Assignment of categories for each specific mission/body is to take into account current scientific knowledge based on recommendations from scientific advisory groups

• Examples of specific measures include:
  – Constraints on spacecraft operating procedures
  – Spacecraft organic inventory and restrictions
  – Reduction of spacecraft biological contamination
  – Restrictions on the handling of returned samples
  – Documentation of spacecraft trajectories and spacecraft material archiving

W. Peet, 1967
Planetary Protection

Cleaning Spacecraft Right: Viking

The Inquisition approach...

Dry Heat Microbial Reduction works

- The Viking Landers were estimated to carry ~30 viable spores
- This means they *needed* $10^{-6}$ in post-launch factors to meet the probability of contamination requirement
Juno Implementation Approach

Juno proposed to meet planetary protection requirements by avoiding impact with Europa (and other Galilean satellites) via an End-of-Mission Deorbit Maneuver.

To document a $1 \times 10^{-4}$ probability of contamination, Juno considered a range of factors:

- How reliable is the spacecraft, over the mission phases during which Europa is in jeopardy?
- How long will organisms survive?
  - Bioburden at launch
  - Survival of contaminating organisms
- How likely is an Europa encounter?
- Can organisms survive the impact?
## JUNO Allocations and Estimates

<table>
<thead>
<tr>
<th>Item</th>
<th>Current Best Estimate</th>
<th>Requirement Allocation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Failure Risk Analysis:</strong> Probability that spacecraft failure prevents deorbit burn</td>
<td>0.045</td>
<td>≤0.1</td>
</tr>
<tr>
<td><strong>Mission Design:</strong> Probability of impact of a non-sterile spacecraft (L3 Mission System)</td>
<td>0.005</td>
<td>≤0.015</td>
</tr>
<tr>
<td><strong>Spacecraft/Europa Impact Analysis:</strong> Probability of contamination in the event of an impact</td>
<td>&lt;0.04</td>
<td>0.06</td>
</tr>
<tr>
<td>Probability of contamination of the Euroman Ocean</td>
<td>&lt;9x10^{-6}</td>
<td>9x10^{-5}</td>
</tr>
<tr>
<td>Requirement</td>
<td></td>
<td>&lt;1x10^{-4}</td>
</tr>
</tbody>
</table>

Each individual factor was in the range of percent – all together, they reached 10^{-5}
Preventing Contamination: Flexibility within a Framework

- Each mission scenario is unique, and small factors can play a significant role in compliance.
- The ability to tailor reduction factors appropriately allows increased resolution when aspects of compliance are more challenging.
- Assessing reduction factors in the context of mission phases provides independence in time.
- Detailed analysis progressing from early to late mission phases ensures that ‘margin’ is not wasted.
- ‘Probability of Growth’ is the last factor to consider – we’ve been wrong too many times before.
Current View: SSB Icy Bodies Report

Alles sollte so einfach wie möglich gemacht werden, aber nicht einfacher.

Albert Einstein

Everything should be made as simple as possible, but not simpler.
Current and Upcoming Missions

• Several missions in operation and in preparation have planetary protection considerations to watch
  – The Dawn asteroid orbiter mission must avoid possible contamination of Ceres
  – Each of the Discovery selection competitors have planetary protection implementation challenges, but they are well-understood
  – The OSIRIS-REx asteroid sample return mission faces organic contamination constraints driven by science, but relevant to future planetary protection implementation concerns
  – The MAVEN Mars orbiter mission plans to implement the bioburden control option to meet planetary protection requirements: analysis currently under review
New Frontiers Program

Future Missions Have Significant Constraints
Technologies Keep Changing

• What technology developments can facilitate compliance with planetary protection requirements?

• Are new developments needed? In what areas?

• How can NASA ensure that spacecraft and instrument developers understand design issues associated with planetary protection?

• What can be done to ensure that NASA’s technology investments are compatible with these needs?

Planetary protection works much better when included from the start
Planetary Protection Research

- Element of SMD ROSES call; solicits research that isn’t covered by Astrobiology in these areas (13 grants total)
  - Characterizing the limits of life in laboratory simulations of planetary environments or in appropriate Earth analogs, particularly studies of the potential, distribution and dynamics of organism[s] (4 grants)
  - Modeling of planetary environmental conditions and transport processes that could permit mobilization of spacecraft-associated contaminants (2 grants)
  - Development or adaptation of modern molecular analytical methods to rapidly detect, classify, and/or enumerate the widest possible spectrum of Earth microbes ... and (4 grants)
  - New or improved methods, technologies, and procedures for spacecraft sterilization (3 grants)
Programmatic Concerns

• An increasing number of mission concepts target locations of concern for planetary protection, both Mars and Outer Planets

  – Technology development for planetary protection, beyond basic research, has historically been left to missions: better coordination in planetary protection technology development would facilitate efficient use of resources (PPR is not enough...)

  – Ongoing planning for human spaceflight beyond Earth orbit highlights the need to elaborate, at the level of NASA policy, the guidelines for human exploration that were accepted by COSPAR in 2008

  – Increasing interest in exploration activities by multiple national and private organizations raises a range of concerns: e.g., international cooperation, commercial exploration, and historical/environmental protection
Planetary protection goals remain the same: keep it clean...

Warning: The Planetary Protection Officer has determined that drilling may be hazardous to your health and your future ability to return to Earth.

But humans will carry microbes to Mars – what do we do when astronauts get sick?
Planetary Protection and Commercial Spaceflight

Application of planetary protection policy to non-governmental entities is still being developed. Examples include:

- The Google Lunar X-Prize will be awarded for the successful completion of the first privately-led mission to the Moon

- Space-X would like to send Dragon to Mars...

CONGRATULATIONS!
Facilitating International Cooperation

- Planetary protection preparation for upcoming international mission concepts is ongoing – ESA and NASA continue working together on planetary protection technology and requirements development
  - Joint development of specific needs (DHMR, VHP, etc.)
  - Multi-year effort to update the Life Detection Protocol
  - Coordination of agency advisory committee activities
  - Integrated activities for categorization and monitoring of joint missions as they develop

Protecting the Earth *must* be an international endeavour...
Overview and Summary of Life Detection Protocol Update Workshop

C. Conley
G. Kmínek

1 May 2012
Public **Conference** encouraged discussion of what it means to ‘detect life’ and develop a community consensus regarding what is required for a credible claim of life detection.

By-invitation **Workshop** addressed the potential for measurements that address broader scientific questions to be used also for planetary protection purposes to meet criteria for release of samples from containment, which could minimize use of scarce samples and duplication of effort.

**Workshop Objectives:**
- Evaluate current and possible scientific investigations that could identify signs of viable, extant life in samples returned from Mars
- Assess the state-of-the-art of available technologies and identify areas that require future work
- Discuss efficient phasing of planetary protection measurements in the context of proposed scientific analyses, to maximize efficient use of resources
- Identify needed improvements in sample preparation, detection technologies, and controls/blanks that would increase confidence in the results
Assumptions: looking for life based on carbon chemistry that happens at Mars-surface temperature and pressure, on human-detectable timescales (i.e., water soluble).

Information addressing the properties of life as defined above might be found by measuring:

1) Structure and morphology of samples, at macro and micro scales
2) Chemical composition and heterogeneity of samples
3) Environmental and thermodynamic context of samples and interesting features within

Two competing hypothesis should be tested:

1) There is no life in the samples.
2) There is Mars life in the samples.

DATA will be collected: interpretation could provide 'strong biosignatures,' 'possible biosignatures,' 'indicators of abiotic processes,' or 'indicators of Earth contamination' – depending on which hypotheses the data support or refute.
Testing competing ‘null’ hypotheses is an effective strategy to address both scientific and planetary protection interests. Hypotheses are:

1) There is no life in the samples.
2) There is Mars life in the samples.

Data will be collected: these data may be equally relevant to ‘science’ and ‘planetary protection.’ Interpretation of collected data will guide policy decisions regarding sample safety and subsequent handling, as well as inform scientific research.

Characterization of measurements as 'strong biosignatures,' 'possible biosignatures,' 'indicators of abiotic processes,' or 'indicators of Earth contamination' could be useful.

A decision analysis strategy based on Bayesian statistics could be used to direct sequences of investigations to increase confidence in conclusions as input to policy.

Sample handling and containment are key technology needs:

1) Non-destructive imaging should be used to identify subsamples for further analysis
2) Significant improvements in clean subsampling capabilities are needed
3) Remote micromanipulation could greatly facilitate clean sample handling
More Players in the Game...

- The landscape of space exploration is changing rapidly – more countries are interested in space exploration, and private corporations have improving capabilities.
- What additional concerns are raised by the participation of more and non-governmental entities?
- How can these be mitigated? Used advantageously?
- To what extent can existing national and international frameworks be used to address issues?
- What can be done to ensure that relevant perspectives are collected and, to the extent possible, addressed?

The goals of planetary protection remain to protect science and the Earth.
The Basic Rationale for Planetary Protection Precautions
(as written by Bart Simpson, Dec. 17, 2000, “Skinner’s Sense of Snow”)

Science class should not end in tragedy....
